

GABA

1. Where in the CNS do we find GABA? What is it doing?
2. Draw the enzymatic synthesis and inactivation of GABA.
Note: names of precursors, enzymes, co-factors, etc. are sufficient. It is NOT necessary to draw the chemical structures.
3. Describe / Draw a representation of the GABA_A ionotropic receptor. How many subunits are required? What ion(s) permeate the activated receptor? Indicate where the following bind to the GABA_A receptor: BDZ, barbiturates, NAM, GABA, neurosteroids.
4. GABA receptors are either metabotropic (GABA_B) or ionotropic (GABA_A), and they have different roles in neurotransmission. Compare and contrast the functions of the types of GABA receptors.

GABA _A	GABA _B	
	<u>Postsynaptic</u>	<u>Presynaptic</u>
